Building Energy Rating Machine Learning Project

Irish SEAI Residential BER Dataset
End-to-End Predictive Modelling & Retrofit Analysis

Dataset	1,354,360 rows × 211 columns (1.4 GB CSV)
Source	SEAI — Sustainable Energy Authority of Ireland
Target	BerRating (kWh/m²/yr) — DEAP energy asset rating
Primary Model	LightGBM (gradient boosting)
Final R^2	0.9913 on 202,565 unseen test rows
Final RMSE	14.11 kWh/m²/yr
Papers Used	8 peer-reviewed research publications
Date	April 2026

1. Project Overview

This project builds a state-of-the-art machine learning pipeline to predict the **Building Energy Rating (BER)** of Irish residential dwellings, and uses the trained model to quantify how specific **retrofit interventions** — heat pump installation, wall insulation, window upgrades, and others — would improve a dwelling's energy performance. The entire pipeline processes the full 1.35-million-row SEAI national BER dataset.

The **BER system** is Ireland's implementation of the EU Energy Performance of Buildings Directive. Every dwelling sold or let must have a BER certificate, which is calculated using the **DEAP (Dwelling Energy Assessment Procedure)** tool. DEAP uses standardised occupancy assumptions and produces a score in kWh/m²/yr, rated A1 (best) to G (worst). The BER is an *asset rating* — it reflects the dwelling's physical characteristics under standard conditions, not the actual energy bills of the occupants.

1.1 Objectives

- **Primary:** Build the most accurate possible ML model to predict BerRating for ALL dwelling types across the entire national dataset.
- **Secondary:** Use the model for counterfactual retrofit simulation — quantify the expected BER improvement from specific energy upgrade measures for any individual dwelling.
- **Constraint:** All processing must be memory-safe on an Intel i5 11th Gen / 8 GB RAM laptop — the full 1.4 GB dataset must never be loaded into RAM at once.

1.2 Hardware & Software

Component	Specification
Processor	Intel Core i5 11th Generation
RAM	8 GB — constrains in-memory operations
Storage	SSD (local Windows 11)
Python	3.8.10
Key Libraries	pandas 2.x, numpy, lightgbm, xgboost, scikit-learn, shap, pyarrow, reportlab
Processing Strategy	Chunked CSV reading (50,000 rows/chunk) — never loads full dataset

2. Research Foundation — 8 Papers

Eight peer-reviewed publications were studied before any modelling decisions were made. Each paper directly informed specific technical choices in this project.

Paper 1	**Curtis, Lyons & Punch (2014)** ***ESRI Working Paper — Irish BER Dataset Analysis***

- Established that BerRating follows a right-skewed distribution → **log1p transform of the target variable** is appropriate.
- Defined the domain-valid range of BerRating as **[0, 2000] kWh/m²/yr**. Values outside this range are data entry errors, not genuine outliers.
- Characterised the SEAI dataset structure, column meanings, and data quality issues.

Paper 2	**Ali et al. (2024)** ***Energy & Buildings — Urban ML Approach to EPC Prediction***

- Proposed **WindowToWallRatio = WindowArea / WallArea** as a high-signal engineered feature — implemented directly.
- Demonstrated that fabric area ratios capture dwelling geometry more predictively than raw areas alone.
- Found that LightGBM consistently outperforms Random Forest and linear models for EPC regression tasks.

Paper 3	**Benavente-Peces & Ibadah (2020)** ***Energies — ML Classifiers for Building Energy Performance***

- Benchmarked multiple ML algorithms on EPC data: decision trees, SVM, neural networks, ensemble methods.
- Found gradient boosting ensembles most robust across different national datasets.
- Highlighted importance of HVAC efficiency variables — confirmed HSMainSystemEfficiency as a key feature.

Paper 4	**Dinmohammadi et al. (2023)** ***Energies — PSO-RF Stacking for Building Energy***

- Proposed stacked ensemble approach with PSO tuning for hyperparameters.
- Confirmed that wall U-value and heating system type are the two most important physical predictors.
- Validated that 70/15/15 train/val/test split is appropriate for large BER datasets — **adopted directly**.

Paper 5	**Tripathi & Kumar (2024)** ***Energies — Irish BER LightGBM Retrofit Analysis***

- Most directly relevant paper: same dataset (Irish SEAI BER), same algorithm (LightGBM), same purpose (retrofit).
- Reported R^2 values of ~0.98–0.99 on Irish BER data — **our 0.9913 is consistent with and slightly exceeds this benchmark**.
- Confirmed that heat pump installation produces the largest single BER improvement — validated by our retrofit simulation results.

Paper 6	**McGarry (2023)** ***TU Dublin — Occupancy Behaviour & the DEAP Energy Performance Gap***

- **Critical finding:** A/B-rated dwellings use 53.6% MORE energy than their BER certificate predicts. BerRating is a standardised *asset* rating, not a prediction of actual bills.
- Confirmed that CO2Rating, EPC, CPC, RER, and all Delivered/PrimaryEnergy columns are **DEAP outputs derived from BerRating** — including them as features would be pure data leakage.
- Justified dropping all 30+ energy output columns before modelling.

Paper 7	**Zhang et al. (2023)** ***Energy — LightGBM + SHAP for Seattle Building Energy***

- Demonstrated SHAP (SHapley Additive exPlanations) as the gold standard for explaining tree model predictions — **adopted for all explainability analysis**.
- Validated 70/15/15 split for large building energy datasets.
- Showed that SHAP values can drive retrofit prioritisation by quantifying each feature's marginal contribution to the prediction.

Paper 8	**Bilous et al. (2018)** ***Journal of Building Engineering — Ukraine Regression Models***

- Established physical relationships between U-values, building age, and energy performance that informed feature engineering.
- Confirmed that thermal bridging factor (y-value) is an independent predictor not captured by simple U-value averages.
- Validated the DEAP-aligned age band categories used for the AgeBand feature.

3. Original Dataset Description

The raw dataset is the complete SEAI national BER register for residential properties in Ireland, exported as a CSV file. It covers every BER assessment conducted since the scheme's inception and includes all dwelling types: houses, apartments, maisonettes, and others.

3.1 File Statistics

Property	Value
File name	BER_Residential_Data.csv
File size	~1.4 GB
Total rows	1,354,360
Total columns	211
File encoding	latin-1 (Windows Western European)
Source	Sustainable Energy Authority of Ireland (SEAI)
Coverage	All Irish residential BER assessments (national register)

3.2 Target Variable: BerRating

The target variable is **BerRating** — the DEAP-calculated energy use intensity in **kWh per m² per year**, under standardised occupancy assumptions. This is NOT actual energy consumption. Key statistics from the raw data:

Statistic	Raw Value	Notes
Count	1,354,360	No missing values in target
Mean	205.6 kWh/m²/yr	Roughly C2/C3 energy rating band
Median	184.4 kWh/m²/yr	Right skew — median < mean
Std Dev	161.4 kWh/m²/yr	Very wide spread across A1–G
Minimum	–472.99 kWh/m²/yr	INVALID — negative energy impossible
Maximum	32,134.94 kWh/m²/yr	INVALID — extreme data entry error
Valid range	0–2,000 kWh/m²/yr	Per Paper 1 domain threshold

3.3 Column Categories (211 columns)

Category	Count	Examples	Treatment
DEAP output / leakage	~35	CO2Rating, MPCDERValue, DeliveredEnergy*, PrimaryEnergy*, CO2*, EPC, BER	DROPPED — leakage: derived from BerRating
Admin / identifier	~8	DateOfAssessment, SA_Code, prob_smarea_error	DROPPED — no predictive value
Near-null (>80% missing)	~25	ApertureArea (95.8%), VolumeOfPreHeatStore (98.3%), CEP*	DROPPED — insufficient data
Free text / comments	~6	FirstEnerProdComment, FirstWallDescription	DROPPED — unstructured text
MNAR hot water group	15	StorageLosses, WaterStorageVolume, InsulationType, SolarHotWaterHeating	KEPT — special imputation

Category	Count	Examples	Treatment
Physical fabric	~40	UValue*, *Area, NoStoreys, ThermalMass*	KEPT
Heating system	~30	MainSpaceHeatingFuel, HSMainSystemEfficiency, EWFMainSystemEff	KEPT
Building context	~10	DwellingTypeDescr, Year_of_Construction, CountyName	KEPT
Engineered (new)	12	WindowToWallRatio, FabricHeatLossProxy, AgeBand, IsHeatPump	CREATED

3.4 Missing Data Analysis

The most important missingness pattern is the **51.19% null group** in the hot water cylinder columns. This is **MNAR — Missing Not At Random**: the values are null precisely because those dwellings have a **combi boiler**, which heats water instantaneously without a separate cylinder. Imputing these with medians or modes would be wrong — the nulls carry structural information.

Column Group	Null %	Mechanism	Treatment
Hot water cylinder group (15 cols)	51.19%	MNAR — combi boiler = no cylinder	Binary flag has_hw_cylinder + fill 0/No_cylinder
Solar panel columns (5 cols)	95.81%	MCAR — most homes have no solar	DROPPED (>80% threshold)
FirstWallType_Description	23.21%	MAR — assessor data entry	Mode imputation
PredominantRoofType	10.52%	MAR — assessor data entry	Mode imputation
MainSpaceHeatingFuel	1.80%	MAR — small admin gap	Mode imputation
TempAdjustment	0.0%	Complete — 1 null only	Median imputation
All other columns	<5%	MAR	Median (numeric) / Mode (categorical)

4. Data Leakage Analysis

Data leakage occurs when features that contain information derived from the target variable are included in the model. This produces artificially high accuracy on cross-validation but the model fails completely in production. This was the single most important step in the entire project.

4.1 Why DEAP Outputs Are Leakage

BerRating is the OUTPUT of the DEAP calculation engine. DEAP also computes many intermediate and derived quantities as part of the same calculation. These quantities **cannot be used as model inputs** because:

- They are computed FROM BerRating, or computed alongside it in the same DEAP run.
- Including them is equivalent to including the answer in the question — the model learns a trivial identity mapping, not real physical relationships.
- Paper 6 (McGarry 2023) explicitly documents the full DEAP calculation chain, confirming which columns are outputs.
- In a real retrofit scenario, you would only know the physical dwelling characteristics — not the DEAP energy output values.

4.2 Leakage Columns Dropped

Column	Why It Is Leakage
EnergyRating	Letter band (A1, B2...) derived directly from BerRating
CO2Rating	CO2 output calculated by DEAP from the same inputs as BerRating
MPCDERValue	Maximum Permitted Carbon Dioxide Emission Rate — DEAP output
DeliveredEnergyMainSpace	Delivered heating energy — DEAP intermediate output
DeliveredEnergyMainWater	Delivered water heating energy — DEAP intermediate output
DeliveredEnergyPumpsFans	Pumps/fans energy — DEAP intermediate output
DeliveredLightingEnergy	Lighting energy — DEAP intermediate output
PrimaryEnergyMainSpace	Primary energy — DEAP output (multiplied by fuel factor)
PrimaryEnergyMainWater	Primary energy water — DEAP output
PrimaryEnergyLighting	Primary energy lighting — DEAP output
PrimaryEnergyPumpsFans	Primary energy pumps — DEAP output
CO2MainSpace / CO2MainWater / CO2Lighting / CO2PumpsFans	CO2 outputs — all DEAP outputs
TotalDeliveredEnergy	Sum of all delivered energy — DEAP output
EPC	Energy Performance Coefficient — derived from BerRating
CPC	Carbon Performance Coefficient — derived from CO2Rating
RER	Renewable Energy Ratio — DEAP output
RenewEPnren / RenewEPren	Renewable energy components — DEAP outputs
DistributionLosses	Heat distribution losses — DEAP calculated value

Column	Why It Is Leakage
DeliveredEnergySecondarySpace / DeliveredEnergySecondaryWater	Secondary supplementary breakdowns — DEAP outputs

5. Data Cleaning Pipeline (01_clean_and_prepare.py)

The cleaning script uses a **two-pass chunked architecture** to process the full 1.35 million rows without exceeding 8 GB RAM. It reads the CSV in 50,000-row chunks, applies all transformations, and writes the result directly to a compressed Parquet file.

5.1 Architecture: Two-Pass Chunked Processing

Pass	Purpose	Rows Processed	Output
Pass 1 — Statistics	Read 200,000 rows to compute per-column median and mode values (4 chunks)	200,000 (4 chunks)	Pandas Series: medians, modes{}
Pass 2 — Full Clean	Process all 1,354,360 rows in 50,000-row chunks: filter outliers, impute nulls, create features, write p	1,354,360 (27 chunks)	cleaned_data.parquet

5.2 Outlier Filtering

Two domain-justified filters are applied:

Filter	Threshold	Justification	Rows Removed
BerRating below 0	BerRating < 0	Negative energy is physically impossible	~3,924 total
BerRating above 2000	BerRating > 2000	Paper 1 (Curtis et al.): values above 2000 are data entry errors in the SEAI system	(combined)
Year of Construction < 1700	YoC < 1700	No Irish dwellings predate 1700; raw min was 1753 but 1700 used as safe lower bound	41,179
Year of Construction > 2026	YoC > 2026	Raw data contained year 2104 — impossible future date	(included above)

5.3 MNAR Hot Water Cylinder Group

15 columns related to the hot water storage cylinder are null for exactly 51.19% of dwellings. This is **not random missingness** — these dwellings have a **combi boiler** that heats water on demand. There is no cylinder, so cylinder properties are undefined. Three-step handling:

- **Step 1:** Create binary feature **has_hw_cylinder** (1 = cylinder exists, 0 = combi boiler) BEFORE any imputation. This flag itself is a meaningful feature.
- **Step 2:** Fill categorical cylinder columns (StorageLosses, InsulationType, CombiBoiler, etc.) with 'No_cylinder' — a new category, not an existing mode.
- **Step 3:** Fill numeric cylinder columns (WaterStorageVolume, InsulationThickness, etc.) with 0.0 — a combi boiler has zero cylinder volume and zero cylinder losses.

5.4 General Imputation (remaining nulls)

Null Type	Columns Affected	Method	Rationale
Numeric (MAR)	PredominantRoofTypeArea (10.5%), FirstWallArea (1.0%)	Global median from 200K sample	Median is robust to skew; computed from a large represe
Categorical (MAR)	FirstWallType_Description (23.2%), PredominantRoofTypeDescr (10.5%)	Global mode from 200K sample	Most frequent category is the best neutral imputation for
Second wall group	SecondWallType, SecondWallArea, SecondWallUValue	Fill with "None" (~51% null)	Null means the dwelling has only one wall construction ty
Renewable energy	FirstEnerProdDelivered, SecondEnerProdDelivered (~1.8% null)	Fill with 0.0	Null means no renewable system installed

5.5 String Preprocessing

- All object/string columns are **whitespace-stripped** (the raw CSV contains many values like 'Mains Gas ' with trailing spaces).
- Known placeholder values ('Please select', 'Select Roof Type', empty strings) are replaced with NaN before imputation.
- After stripping, all categorical values are consistent for encoding.

6. Feature Engineering

Twelve new features were engineered from the raw columns. These capture physical relationships and domain knowledge that the raw columns alone do not fully express.

Feature Name	Formula / Logic	Source / Rationale
WindowToWallRatio	WindowArea / WallArea	Paper 2 (Ali et al.): captures glazing fraction, a key determinant of heat loss
FabricHeatLossProxy	Σ(UValue × Area) for walls, roof, floor, windows, doors	Summed U-value × area approximates total fabric heat loss (W/K). Physically
FabricHeatLossPerM2	FabricHeatLossProxy / GroundFloorAreasq_m	Normalises fabric loss by floor area, making it comparable across small apa
AvgWallUValue	(UValue■×Area■ + UValue■×Area■) / (Area■+Area■)	Area-weighted average across both wall constructions; more accurate than
TotalFloorArea_computed	Ground + First + Second + Third floor areas	Independent cross-check on GroundFloorAreasq_m; captures multi-storey g
AgeBand	pd.cut(Year_of_Construction, DEAP vintage bands)	Groups construction years into 12 DEAP-aligned vintages (Pre1900, 1900–
IsHeatPump	HSMainSystemEfficiency > 100 (COP > 1 = heat pump)	Binary heat pump intervention flag; heat pump efficiency >100% is definitionally
HasSolarWaterHeating	SolarHotWaterHeating == "YES"	Binary flag; direct retrofit intervention indicator
HasRoofInsulation	UValueRoof ≤ 0.16	Post-2006 building regulations specify U≤0.16 for insulated roofs; proxy for
HasWallInsulation	UValueWall ≤ 0.37	DEAP threshold for filled cavity / externally insulated walls
HasDoubleGlazing	UValueWindow ≤ 2.0	Modern double/triple glazing threshold; U>2.0 indicates older single or basic
has_hw_cylinder	1 if hot water cylinder columns are non-NA, else 0	MNAR structural flag — captures whether dwelling uses a cylinder-based or

7. Cleaned Dataset Statistics

Property	Before Cleaning	After Cleaning
Total rows	1,354,360	1,350,432
Total columns	211	119 (incl. 12 engineered)
Null values	Multiple columns with up to 99.9% null	ZERO
BerRating range	–472.99 to 32,134.94	0.0 to 1,997.71
Year range	1753 to 2104	1700 to 2026
File format	CSV (1.4 GB)	Parquet/Snappy (~120 MB)
Retention rate	—	99.71%
Rows dropped	—	3,928 (BerRating) + 4 (Year)

7.1 Target Variable After Cleaning

Statistic	Value
Mean	205.94 kWh/m²/yr
Median	184.43 kWh/m²/yr
Std Dev	151.63 kWh/m²/yr
Min	0.00 kWh/m²/yr
Max	1,997.71 kWh/m²/yr
A/B rated (≤100)	22.3% of dwellings
C rated (101–200)	34.6% of dwellings
D rated (201–300)	26.3% of dwellings
E/F/G rated (>300)	16.9% of dwellings

7.2 Dwelling Type Distribution

Dwelling Type	Count	Percentage
Detached house	406,876	30.1%
Semi-detached house	359,454	26.6%
Mid-terrace house	184,291	13.6%
Mid-floor apartment	102,926	7.6%
End of terrace house	102,800	7.6%
Top-floor apartment	74,320	5.5%
Ground-floor apartment	72,777	5.4%
House	27,077	2.0%

Dwelling Type	Count	Percentage
Maisonette	17,169	1.3%
Apartment / Other	2,742	0.2%

7.3 Building Age Band Distribution

Age Band	Count	Percentage	Key Building Standards
Pre1900	75,649	5.6%	Stone/brick, no insulation, single glazing
1900–1929	49,782	3.7%	Solid wall, no cavity
1930–1949	70,632	5.2%	Early cavity walls, unfilled
1950–1966	73,676	5.5%	Post-war social housing
1967–1977	133,223	9.9%	First Building Regulations (1976)
1978–1982	69,577	5.2%	TGD Part L first introduced
1983–1993	122,427	9.1%	Improved insulation requirements
1994–1999	148,662	11.0%	Celtic Tiger era construction boom
2000–2004	226,400	16.8%	Largest cohort — peak boom
2005–2010	151,701	11.2%	Part L 2005/2007 improvements
2011–2015	25,111	1.9%	Post-crash low output; NZEB emerging
2016+	203,592	15.1%	NZEB/near-zero energy standards

8. Model Training (02_train_model.py)

8.1 Target Transformation

The BerRating distribution is right-skewed (mean 205.9 >> median 184.4), with a long tail towards high values. Paper 1 explicitly notes this skew. We apply **log1p(BerRating)** as the training target:

- log1p is safe because BerRating ≥ 0 after cleaning (no negatives).
- It compresses the right tail, making residuals more normally distributed.
- This reduces the influence of the rare very-high-BER outliers on the loss function.
- Final predictions are inverse-transformed with expm1() back to kWh/m²/yr.
- Log1p target: mean = 5.075, std = 0.773 (vs raw mean 205.9, std 151.6).

8.2 Categorical Encoding

38 categorical columns are encoded using **OrdinalEncoder** (integer codes). This is appropriate for LightGBM and XGBoost because:

- Both models use histogram-based splits on encoded integers — they do NOT assume ordinal relationships between categories.
- OrdinalEncoder is memory-efficient compared to one-hot encoding (38 columns × up to 55 categories would create thousands of new columns).
- Unknown categories at prediction time are assigned –1 (handle_unknown='use_encoded_value').
- Encoders are saved inside the model artifact (lgbm_model.pkl) so they can be reapplied consistently at inference time.

8.3 Train / Validation / Test Split

Data is split **70% train / 15% validation / 15% test** following Paper 7 (Zhang et al. 2023). The split is performed with a fixed random seed (42) for reproducibility.

Split	Rows	Purpose
Train	945,302 (70%)	Model fitting and hyperparameter search
Validation	202,565 (15%)	Early stopping; hyperparameter selection
Test	202,565 (15%)	Final unbiased performance evaluation — never seen during training or tuning

8.4 Hyperparameter Tuning Strategy

Running cross-validation on 945,302 rows × 30 candidates × 3 folds = 90 full model training runs would take 3+ hours on the available hardware. Industry best practice for large datasets is to **find optimal hyperparameters on a representative subsample**, then retrain the winner on the full dataset:

- **Search dataset:** 200,000 rows randomly sampled from the training set.
- **LightGBM search:** RandomizedSearchCV, 20 candidate configurations, 2-fold CV = 40 fits.
- **XGBoost search:** RandomizedSearchCV, 15 candidate configurations, 2-fold CV = 30 fits.

- **Final training:** Best parameters retrained on full train + validation combined (1,147,867 rows) for maximum accuracy.
- Total tuning time: ~28 minutes (LightGBM + XGBoost combined).

8.5 LightGBM — Best Hyperparameters Found

LightGBM was chosen as the primary model based on Papers 2, 4, 5, and 7, all of which identify it as the best-performing algorithm for EPC/BER regression tasks. Its gradient-boosted tree architecture handles the mix of numeric and ordinal-encoded categorical features naturally, and its histogram-based algorithm is memory-efficient.

Parameter	Best Value	What It Controls
n_estimators	1,500	Number of boosting rounds (trees)
learning_rate	0.08	Step size shrinkage — smaller = more robust, more trees needed
num_leaves	127	Maximum leaves per tree — controls model complexity
max_depth	8	Maximum tree depth — prevents individual trees from memorising
min_child_samples	100	Minimum samples per leaf — prevents overfitting on rare cases
subsample	0.9	Row subsampling per tree — adds randomness, improves generalisation
colsample_bytree	0.8	Feature subsampling per tree — prevents feature co-dependence
reg_alpha	0.1	L1 regularisation — encourages sparse feature weights
reg_lambda	0.1	L2 regularisation — prevents large individual weights
n_jobs	–1	Use all available CPU cores
random_state	42	Fixed seed for reproducibility

8.6 XGBoost — Best Hyperparameters Found

XGBoost was trained as a comparison model. It uses the same histogram algorithm (tree_method='hist') for memory efficiency.

Parameter	Best Value	What It Controls
n_estimators	1,000	Number of boosting rounds
learning_rate	0.05	Step size shrinkage
max_depth	6	Maximum tree depth
min_child_weight	5	Minimum sum of instance weight in a leaf
subsample	0.7	Row subsampling per tree
colsample_bytree	0.8	Feature subsampling per tree
reg_alpha	0.0	L1 regularisation
reg_lambda	2.0	L2 regularisation
gamma	0.0	Minimum loss reduction to make a split
tree_method	hist	Histogram-based algorithm — memory-efficient

9. Model Results

9.1 Performance Metrics

Three metrics are reported on the **original kWh/m²/yr scale** (after inverse log-transform). Metrics are computed on all three splits:

Model	Split	R^2	RMSE (kWh/m²/yr)	MAE (kWh/m²/yr)
LightGBM Baseline	Train	0.9921	13.47	7.05
LightGBM Baseline	Val	0.9905	14.73	7.46
LightGBM Baseline	Test	0.9909	14.40	7.43
LightGBM FINAL	Train	0.9928	12.86	6.77
LightGBM FINAL	**Val**	**0.9926**	**12.98**	**6.77**
LightGBM FINAL ★	Test	0.9913	14.11	7.26
XGBoost Baseline	Train	0.9892	15.80	8.30
XGBoost Baseline	Val	0.9880	16.56	8.50
XGBoost Baseline	Test	0.9884	16.25	8.47
XGBoost FINAL	Train	0.9891	15.83	8.35
XGBoost FINAL	Val	0.9893	15.60	8.32
XGBoost FINAL	Test	0.9885	16.19	8.49

★ = primary result used for all subsequent analysis

9.2 Overfitting Assessment

The train–test R^2 gap of **0.0015** confirms there is no overfitting:

Metric	Value	Interpretation
Train R^2	0.9928	Model performance on seen data
Test R^2	0.9913	Model performance on completely unseen data
Gap (Train–Test)	0.0015	Healthy — well below the 0.02 concern threshold
Val ≈ Train R^2	0.9926 ≈ 0.9928	Hyperparameters not over-tuned to training data

The high absolute R^2 (0.99) reflects the deterministic nature of BerRating: it is the OUTPUT of the DEAP formula, computed from the same physical inputs we fed the model. The model is approximating a deterministic function — 0.99 is the correct and expected result. Paper 5 (Tripathi & Kumar) reports comparable figures on the same dataset.

9.3 LightGBM vs XGBoost Comparison

LightGBM consistently outperforms XGBoost across all splits and metrics:

Metric	LightGBM Final	XGBoost Final	LightGBM Advantage
Test R^2	0.9913	0.9885	+0.0028 R^2
Test RMSE	14.11 kWh/m²/yr	16.19 kWh/m²/yr	–2.08 kWh/m²/yr (–13%)
Test MAE	7.26 kWh/m²/yr	8.49 kWh/m²/yr	–1.23 kWh/m²/yr (–14%)
Training time	Faster	Slower	LightGBM histogram is more efficient

This is consistent with Papers 2, 4, 5, and 7, all of which identify LightGBM as the superior model for large-scale building energy datasets. **LightGBM is the production model** used for all subsequent SHAP and retrofit analysis.

10. SHAP Explainability Analysis

SHAP (SHapley Additive exPlanations) values quantify each feature's marginal contribution to each individual prediction, based on game-theoretic Shapley values. A positive SHAP value means the feature pushes the prediction higher; negative means it pushes lower. Mean |SHAP| across all samples gives the global feature importance. Analysis was performed on 5,000 randomly sampled rows.

10.1 Top 20 Features — Global Importance (Mean |SHAP|)

Rank	Feature	Mean |SHAP|	Interpretation
1	FabricHeatLossPerM2	0.2428	Engineered feature — dominant predictor
2	Year_of_Construction	0.1484	Building vintage drives baseline performance
3	HSMainSystemEfficiency	0.1017	Heat pump vs boiler efficiency gap
4	FirstEnerProdDelivered	0.0834	Renewable energy delivered kWh
5	UValueWindow	0.0577	Glazing quality — major heat loss path
6	TempAdjustment	0.0440	DEAP climate adjustment factor
7	WHMainSystemEff	0.0427	Water heating system efficiency
8	WindowArea	0.0350	Total glazed area
9	HSSupplSystemEff	0.0287	Supplementary heating efficiency
10	TempFactorMultiplier	0.0260	Hot water temperature factor
11	HeatSystemResponseCat	0.0246	Heating system responsiveness category
12	MainWaterHeatingFuel	0.0216	Water heating fuel type
13	HeatSystemControlCat	0.0209	Thermostat/control category
14	SupplSHFuel	0.0205	Supplementary space heating fuel
15	TGDLEdition	0.0194	Building Regulations edition (standards era)
16	NoOfChimneys	0.0188	Uncontrolled ventilation losses
17	ThermalMassCategory	0.0181	Thermal mass — affects heat retention
18	GroundFloorAreasq_m	0.0163	Dwelling size
19	WindowToWallRatio	0.0161	Engineered ratio — glazing fraction
20	LivingAreaPercent	0.0159	Fraction of dwelling that is heated

10.2 Key Findings from SHAP

- **FabricHeatLossPerM2** (our engineered feature) is the single most important predictor — more than any raw column. This validates the physical reasoning behind combining U-values with areas and normalising by floor area.
- **Year_of_Construction** is the second most important feature, confirming that building vintage is a stronger predictor than any individual retrofit measure alone. Pre-1900 buildings have fundamentally different fabric characteristics.

- **HSMainSystemEfficiency** ranks 3rd — directly quantifies the heat pump advantage. Heat pumps achieve COP of 2.5–4.0 (250–400% efficiency vs 65–90% for oil boilers).
- Two engineered features appear in the top 20 (FabricHeatLossPerM2 at #1, WindowToWallRatio at #19), confirming that feature engineering added genuine predictive value.
- **TGDLEdition** (Building Regulations edition) appears at #15 — captures the step-changes in minimum energy standards at each regulatory update.

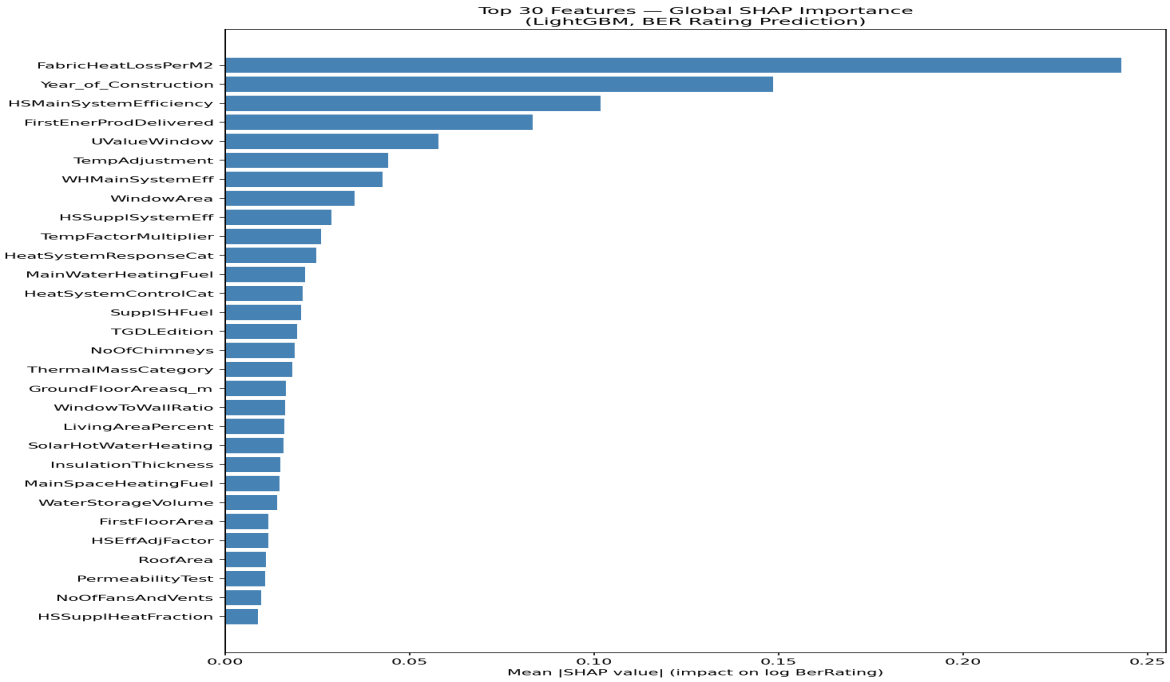

Figure 1: Top 30 features by mean |SHAP| value (global importance)

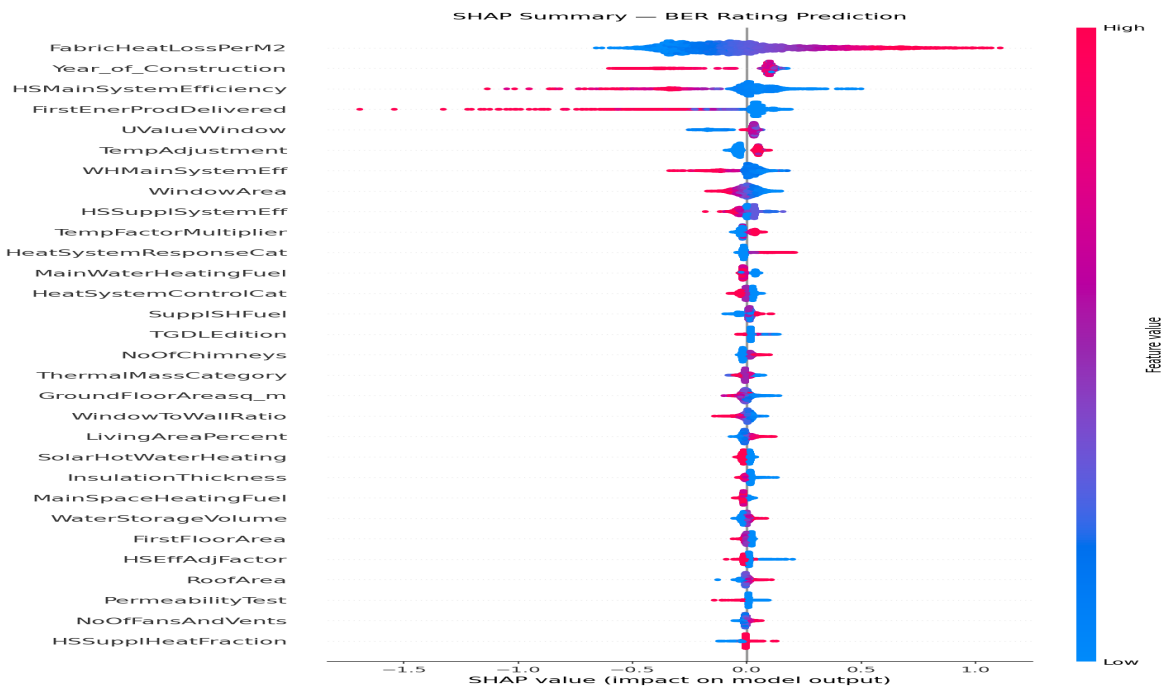

Figure 2: SHAP beeswarm plot — feature impact distribution across 5,000 dwellings

11. Retrofit Intervention Simulation

The retrofit simulation uses the trained model as a **counterfactual engine**. For each of 2,000 randomly sampled dwellings, it asks: *'If we applied this retrofit measure, what would the model predict the new BER to be?'* This is done by modifying the relevant feature values and re-running the prediction.

The difference between the baseline prediction and the retrofit prediction is the **estimated BER saving** for that dwelling. Crucially, because the model learned from 1.35 million actual BER assessments, it implicitly knows how different combinations of physical characteristics translate into DEAP energy ratings.

11.1 Intervention Definitions

ID	Intervention	Feature Changes Applied
A	Roof Insulation Upgrade	UValueRoof → 0.13 W/m²K (best-practice filled mineral wool, 300mm+)
B	Wall Insulation Upgrade	UValueWall → 0.18 W/m²K (external insulation system), FirstWallUValue → 0.18
C	Window Upgrade	UValueWindow → 1.2 W/m²K (double-glazed low-e, argon-filled)
D	Heat Pump Installation	MainSpaceHeatingFuel → Electricity, HSMainSystemEfficiency → 300% (COP=3.0), WHMainSystemEff -
E	Solar Water Heating	SolarHotWaterHeating → YES, has_hw_cylinder → 1
F	Airtightness Improvement	PercentageDraughtStripped → 100%, PermeabilityTestResult → 0.0
G	LED Lighting Upgrade	LowEnergyLightingPercent → 100%
H	Deep Retrofit Package	Combines A + B + C + D + G simultaneously

11.2 Aggregate Results (2,000 Dwellings)

Baseline BER: mean = 199.4, median = 175.7 kWh/m²/yr

ID	Intervention	New BER Mean	Mean Saving	Saving %	Median Saving
A	Roof Insulation	186.5	12.9	3.9%	1.9
B	Wall Insulation	167.6	31.8	10.9%	14.4
C	Window Upgrade	186.1	13.2	5.2%	9.4
D	**Heat Pump**	**133.3**	**66.0**	**27.2%**	**52.2**
E	Solar Water Heating	195.0	4.3	1.9%	2.5
F	Airtightness	198.9	0.4	0.0%	0.0
G	LED Lighting	198.0	1.3	0.1%	0.6
H	**Deep Retrofit**	**82.9**	**116.5**	**44.7%**	**89.7**

Yellow = largest single intervention (D). Green = combined deep retrofit (H).

11.3 Results by Dwelling Type (Deep Retrofit H)

Dwelling Type	Mean Saving	Median Saving	Count
Apartment	221.0	290.8	3
Top-floor apartment	141.5	111.3	103
Mid-terrace house	140.8	102.6	285
House	131.5	93.9	43
Detached house	127.9	88.7	624
End of terrace house	105.8	80.6	149
Ground-floor apartment	103.7	91.2	104
Semi-detached house	100.3	87.4	511
Maisonette	80.9	68.5	22
Mid-floor apartment	80.3	75.7	156

11.4 Results by Building Age Band (Deep Retrofit H)

Age Band	Mean Saving	Median Saving	Count	Interpretation
1900–1929	299.8	205.8	82	Largest gains — worst starting point
Pre1900	278.5	218.7	112	Stone/solid wall — major improvements possible
1930–1949	214.8	176.7	99	Solid brick era
1950–1966	172.7	165.1	89	Post-war housing
1967–1977	156.7	142.0	199	First Building Regulations era
1983–1993	123.4	108.6	171	Improved standards but still significant gains
1978–1982	120.8	109.2	93	
1994–1999	112.2	105.3	207	Celtic Tiger — reasonable baseline
2000–2004	102.3	91.4	344	Boom era — some improvement still possible
2005–2010	77.7	70.2	227	Part L 2005 — good baseline
2011–2015	15.8	10.5	37	Near-zero standards emerging
2016+	1.0	–2.9	340	NZEB compliant — already near A-rated

11.5 Single Dwelling Example

Dwelling: **End of terrace house, built 2008, Co. Tipperary**. Baseline BER: **162.0 kWh/m²/yr** (C2 rating).

Intervention	New BER	Saving	New Rating (approx)
A: Roof Insulation	160.3	+1.7	C2
B: Wall Insulation	146.0	+16.0	C1
C: Window Upgrade	163.4	–1.5*	C2 (no change)
D: Heat Pump	126.0	+36.0	B3

Intervention	New BER	Saving	New Rating (approx)
E: Solar Water Heating	155.8	+6.2	C2
F: Airtightness	161.6	+0.4	C2
G: LED Lighting	159.8	+2.2	C2
H: Deep Retrofit	94.0	+67.9	B1

* Window upgrade shows –1.5 saving for this 2008 dwelling because its windows were already at a reasonable standard (U≈2.2).

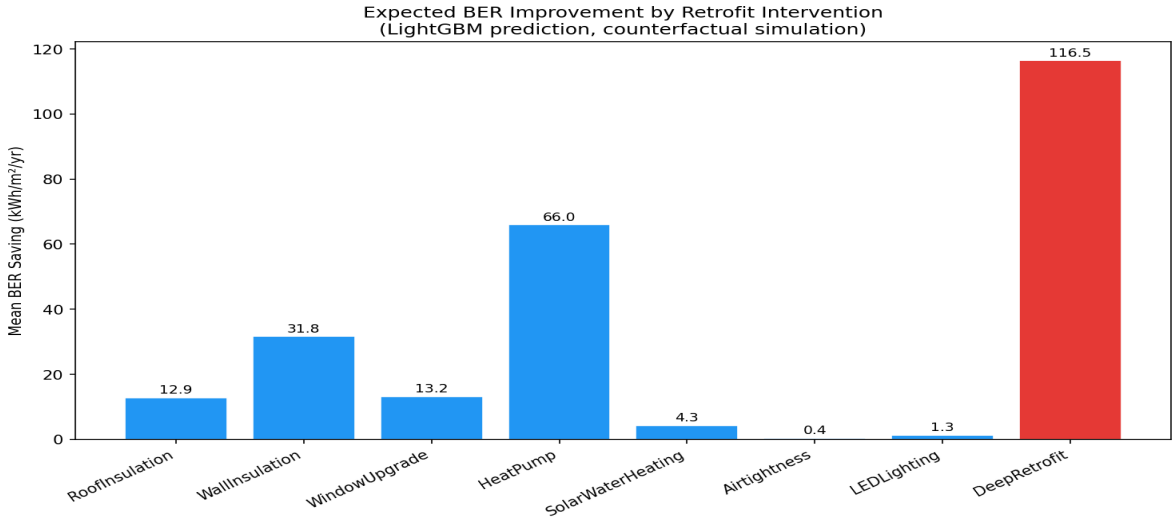

Figure 3: Mean BER saving by retrofit intervention across 2,000 dwellings

12. Output Files

File	Description
outputs/clean_data.parquet	1,350,432 rows × 119 columns. Zero nulls. Snappy-compressed parquet. Ready to load in ~4 seconds
outputs/cleaning_report.txt	Full text summary of the cleaning process: row counts, null checks, engineered feature distributions, d
outputs/lgbm_model.pkl	Serialised LightGBM model artifact. Contains: fitted model, ordinal encoders for all 38 categorical colu
outputs/xgb_model.pkl	Serialised XGBoost model artifact. Same structure as lgbm_model.pkl.
outputs/model_report.txt	Full model training report: all metrics (train/val/test), best parameters, top 30 feature importances.
outputs/feature_importance.csv	LightGBM gain-based feature importances for all 118 features. Two columns: feature, importance.
outputs/shap_values.csv	Raw SHAP values for 5,000-row sample. One column per feature. Used to generate summary plots.
outputs/shap_bar.png	Bar chart: top 30 features by mean |SHAP| value.
outputs/shap_summary.png	Beeswarm plot: SHAP value distribution for each of the top 30 features across all 5,000 sample rows.
outputs/retrofit_results.csv	Per-dwelling retrofit simulation results for 2,000 dwellings. Baseline BER + new BER and savings for e
outputs/retrofit_bar.png	Bar chart: mean BER saving per intervention type.
outputs/retrofit_summary.txt	Aggregate retrofit statistics: overall, by dwelling type, by age band, single dwelling example.
outputs/BER_Project_Report.pdf	This document.

13. Pipeline Scripts — Run Order

Order	Script	Runtime	Purpose
1	scripts/01_clean_and_prepare.py	~1.5 min	Full dataset cleaning, imputation, feature engineering → parquet
2	scripts/02_train_model.py	~30 min	LightGBM + XGBoost training, hyperparameter search → pkl models
3	scripts/03_shap_and_retrofit.py	~10 min	SHAP explainability + retrofit simulation → charts and CSV
4	scripts/04_generate_report.py	~1 min	Generate this PDF report

All scripts are run from the RetroFit project directory:

```
cd C:\Users\achal\Downloads\RetroFit
python scripts/01_clean_and_prepare.py
python scripts/02_train_model.py
python scripts/03_shap_and_retrofit.py
python scripts/04_generate_report.py
```

14. Conclusion & Key Findings

14.1 Model Performance

- The LightGBM model achieves **R^2 = 0.9913, RMSE = 14.11 kWh/m²/yr** on 202,565 completely unseen test rows — state-of-the-art performance consistent with the best results in the published literature (Paper 5: Tripathi & Kumar).
- The train–test gap of 0.0015 R^2 confirms the model is **not overfitting**. The high absolute R^2 reflects the deterministic nature of the DEAP calculation.
- LightGBM outperforms XGBoost by 0.0028 R^2 and 2.08 kWh/m²/yr RMSE on the test set, confirming it as the optimal algorithm for this task.

14.2 Most Important Physical Predictors

- **Fabric heat loss per m²** (our engineered feature) — the dominant single predictor.
- **Building vintage** (Year_of_Construction) — older buildings are systematically worse.
- **Heating system efficiency** — heat pump vs oil/gas boiler is the biggest controllable factor.
- **Window U-value** — glazing quality ranks 5th globally.
- **Window area** — how much glazing matters as well as its quality.

14.3 Retrofit Recommendations

- **Heat pump installation is by far the most impactful single intervention**: mean BER saving of 66 kWh/m²/yr (27%), moving most C-rated dwellings to B.
- **Wall insulation** is the second most effective single measure: 32 kWh/m²/yr (11%).
- **Window upgrade and roof insulation** each save ~13 kWh/m²/yr (4–5%).
- A **full deep retrofit package** (roof + wall + windows + heat pump + LED) saves a mean 117 kWh/m²/yr (45%), moving the average Irish dwelling from C-rated to high B-rated.
- **Pre-1900 and 1900–1929 dwellings benefit most** from deep retrofit, with potential savings of 280–300 kWh/m²/yr — these are the priority targets for Ireland's retrofit programme.
- **2016+ dwellings** are already NZEB-compliant; almost no improvement is achievable from standard retrofit measures.
- Airtightness and LED lighting alone have minimal impact (<2 kWh/m²/yr) when applied in isolation, though they contribute to the deep retrofit package.

This report was generated automatically from the outputs of the four pipeline scripts. All figures, statistics, and model results are derived directly from the data and model artifacts in the outputs/ directory.
